

## UNIT IV – SERIALIZATION AND DESERIALIZATION

### Reading and writing objects using Serialization:

- ✓ In Java, serialization is the process of converting an object's state into a byte stream, while deserialization is the reverse process of recreating the object from that byte stream.
- ✓ This is commonly used to save and retrieve objects from files, send them over a network, or transfer them between systems.

### Steps for reading and writing objects using serialization

#### 1. Implement the Serializable interface:

- ✓ The class of any object you want to serialize must implement the `java.io.Serializable` interface.
- ✓ `Serializable` is a marker interface, meaning it has no methods to implement. It simply marks the class as eligible for serialization.
- ✓ If a superclass is `Serializable`, all its subclasses are automatically `Serializable` as well.

#### 2. Define a serialVersionUID

- ✓ Add a private static final long `serialVersionUID` field to your class.
- ✓ This version number is used to verify that the sender and receiver of a serialized object have compatible class definitions.
- ✓ If you change your class and the `serialVersionUID` is different, a `java.io.InvalidClassException` is thrown during deserialization.

#### 3. Mark fields as transient

- ✓ Use the `transient` keyword to exclude specific fields from the serialization process.

- ✓ This is useful for sensitive data (like passwords) or temporary fields that do not need to be saved to the file.
- ✓ Static fields are not part of an object's state, so they are not serialized by default. The transient keyword has no effect on them.

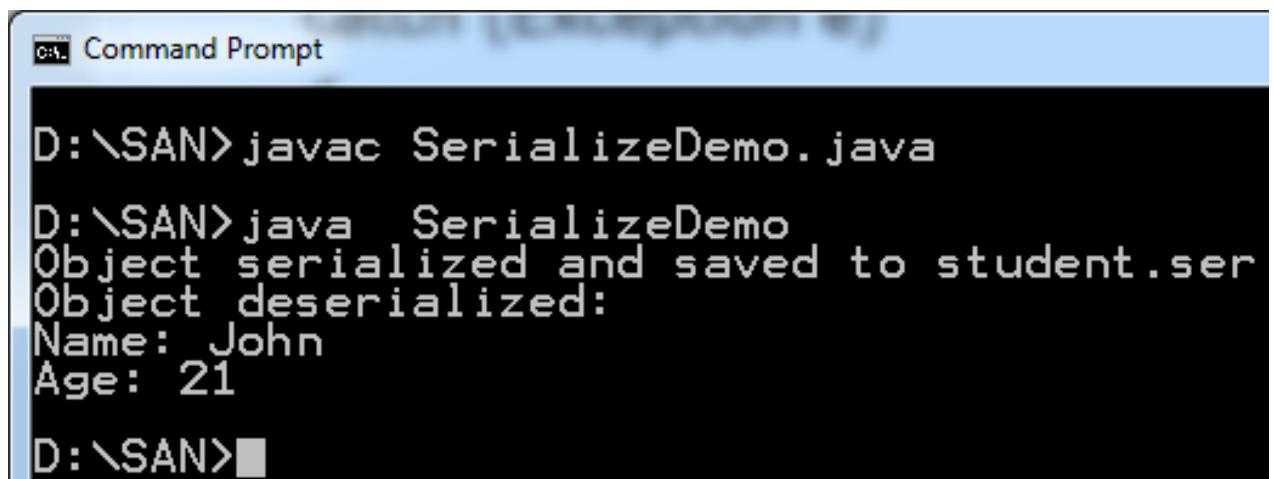

**Example:**

```

import java.io.*;
class Student implements Serializable
{
    String name;
    int age;
    Student(String name, int age)
    {
        this.name = name;
        this.age = age;
    }
}
public class SerializeDemo
{
    public static void main(String[] args)
    {
        try          // SERIALIZATION (Writing object to file)
        {
            Student s1 = new Student("John", 1);
            FileOutputStream fos = new FileOutputStream("student.ser");
            ObjectOutputStream oos = new ObjectOutputStream(fos);
            oos.writeObject(s1); // Write object
            oos.close();
            fos.close();
            System.out.println("Object serialized and saved to student.ser");
        }
        catch (Exception e)
        {
            System.out.println(e);
        }
        try          // DESERIALIZATION (Reading object from file)
        {
            FileInputStream fis = new FileInputStream("student.ser");
            ObjectInputStream ois = new ObjectInputStream(fis);
            Student s2 = (Student) ois.readObject(); // Read object
            ois.close();
            fis.close();
        }
    }
}

```

```
        System.out.println("Object serialized:");
        System.out.println("Name: " + s2.name);
        System.out.println("Age: " + s2.age);
    }
    catch (Exception e)
    {
        System.out.println(e);
    }
}
}
```

**OUTPUT:**

The screenshot shows a Windows Command Prompt window titled "Command Prompt". The command line shows the execution of a Java program. The user first runs "javac SerializeDemo.java" to compile the code. Then, they run "java SerializeDemo" to execute it. The output indicates that an object was serialized and saved to "student.ser". The program then prints "Object serialized" and "Object deserialized". Finally, it prints the name and age of the student: "Name: John" and "Age: 21".

```
D:\SAN>javac SerializeDemo.java
D:\SAN>java SerializeDemo
Object serialized and saved to student.ser
Object deserialized:
Name: John
Age: 21
D:\SAN>
```
