

## 2.6 Graph Laplacians

Labeled graph	Degree matrix
	$\begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 3 & 0 & 0 & 0 & 0 \\ 0 & 0 & 2 & 0 & 0 & 0 \\ 0 & 0 & 0 & 3 & 0 & 0 \\ 0 & 0 & 0 & 0 & 3 & 0 \\ 0 & 0 & 0 & 0 & 0 & 2 \end{bmatrix}$
Adjacency matrix	Laplacian matrix
$\begin{bmatrix} 0 & 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 1 & 1 \\ 0 & 1 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 1 & 1 & 0 \end{bmatrix}$	$\begin{bmatrix} 1 & -1 & 0 & 0 & 0 & 0 \\ -1 & 3 & -1 & 0 & -1 & 0 \\ 0 & -1 & 2 & -1 & 0 & 0 \\ 0 & 0 & -1 & 3 & -1 & -1 \\ 0 & -1 & 0 & -1 & 3 & -1 \\ 0 & 0 & 0 & -1 & -1 & 2 \end{bmatrix}$

Graph Laplacians are core mathematical tools used in graph theory, data science, machine learning, image processing, and network analysis. They help us understand connectivity, flow, clustering, and smoothness on graphs.

### 1. What is a Graph Laplacian?

A Graph Laplacian is a matrix representation of a graph that captures:

- How nodes are connected
- How information diffuses across the graph
- How clusters (communities) are formed

☞ It is derived from:

- **Adjacency Matrix (A)**
- **Degree Matrix (D)**

### 2. Basic Components

#### (a) Adjacency Matrix (A)

- $A_{ij} = 1$  if node  $i$  is connected to node  $j$
- $A_{ij} = 0$  otherwise

Example:

$$A = [0 \ 1 \ 1$$

$$1 \ 0 \ 0$$

$$1 \ 0 \ 0]$$

### (b) Degree Matrix (D)

- Diagonal matrix
- $D_{ii}$  = number of edges connected to node  $i$

Example:

$$\begin{bmatrix} 2 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

### Types

#### 1. Unnormalized Laplacian:

$$L = D - A$$

#### 2. Normalized Laplacian:

- $L_{sym} = I - D^{-1/2}AD^{-1/2}$
- $L_{rw} = I - D^{-1}A$

### Unnormalized Graph Laplacian

#### Definition:

$$L = D - A$$

#### Example:

$$\begin{bmatrix} 2 & -1 & -1 \\ -1 & 1 & 0 \\ -1 & 0 & 1 \end{bmatrix}$$

#### Key Properties:

- ✓ Symmetric
- ✓ Positive semi-definite
- ✓ Small eigenvalues → strong connectivity
- ✓ Zero eigenvalue → number of connected components

#### Interpretation:

Measures how much a node differs from its neighbors.

## Normalized Graph Laplacians

Normalization helps when node degrees vary widely.

### (a) Symmetric Normalized Laplacian

$$L_{sym} = I - D^{-1/2}AD^{-1/2}$$

- ✓ Used in spectral clustering
- ✓ Eigenvalues lie between 0 and 2

### (b) Random Walk Laplacian

$$L_{rw} = I - D^{-1}A$$

- ✓ Related to Markov chains & random walks
- ✓ Used in PageRank and diffusion models

## Intuition Behind Laplacian

Think of the graph as a **rubber sheet**:

- Connected nodes try to stay close
- Laplacian measures tension
- Minimizing Laplacian energy  $\rightarrow$  smooth labels or clusters

Mathematically:

$$x^T L x = \sum_{(i,j) \in E} (x_i - x_j)^2$$

❖ If neighbors have similar values  $\rightarrow$  small energy

## 6. Eigenvalues & Eigenvectors (Very Important)

Eigenvalue	Meaning
0	Graph is connected
Multiple 0s	Multiple components

Small values	Strong clusters
Eigenvectors	Reveal community structure

→ Used in **Spectral Clustering**

## 7. Applications of Graph Laplacians

### ◊ Data Science & ML

- Spectral clustering
- Semi-supervised learning
- Dimensionality reduction (Laplacian Eigenmaps)

### ◊ Network Analysis

- Community detection
- Centrality measures
- Graph partitioning

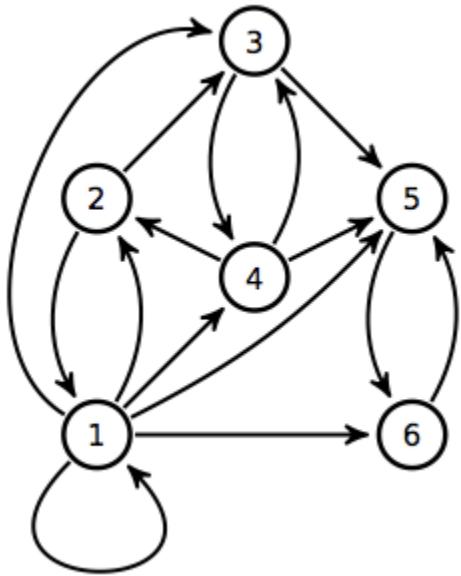

### ◊ Image Processing

- Image segmentation
- Edge detection

### ◊ Physics & Engineering

- Heat diffusion
- Electrical networks

## PageRank Algorithm

PageRank is an algorithm used to rank web pages (nodes) based on their importance in a directed graph.

### Core Idea

A page is important if many important pages link to it.

### Formula

$$PR(i) = \frac{1-d}{N} + d \sum_{j \in In(i)} \frac{PR(j)}{Out(j)}$$

Where:

- $PR(i)$  → PageRank of page  $i$
- $d$  → damping factor (usually **0.85**)
- $N$  → total number of pages

- $In(i)$  → pages linking to  $i$
- $Out(j)$  → outgoing links from page  $j$

### Random Surfer Model

- User follows links with probability  $\mathbf{d}$
- Jumps to a random page with probability  $1 - \mathbf{d}$

### Steps

1. Initialize all pages with equal rank
2. Update ranks using the formula
3. Repeat until values converge

### Properties

- Works on **directed graphs**
- Handles dead ends using damping factor
- Converges to a stable ranking

### Applications

- Web search engines
- Social network influence
- Citation networks
