

## JAVA STRING

In general **string is a sequence of characters**. String is an object that represents a sequence of characters. The **java.lang.String class is used to create string object**. In java, string is basically an object that represents sequence of char values. An array of characters works same as java string. For example:

**Java String class provides a lot of methods to perform operations on string such as com- pare(), concat(), equals(), split(), length(), replace(), compareTo(), intern(), substring() etc.**

The `java.lang.String` class implements `Serializable`, `Comparable` and `CharSequence` interfaces. The `CharSequence` interface is used to represent sequence of characters. It is implemented by `String`, `StringBuffer` and `StringBuilder` classes. It means can create string in java by using these 3 classes.

The string objects can be created using two ways.

1. By String literal
2. By new Keyword

### String Literal

Java String literal is created by using double quotes. For Example:

1. `String s="welcome";`

Each time you create a string literal, the JVM checks the string constant pool first. If the string already exists in the pool, a reference to the pooled instance is returned. If string doesn't exist in the pool, a new string instance is created and placed in the pool. For example:

```
String s1="Welcome";
String s2="Welcome";
```

In the above example only one object will be created. Firstly JVM will not find any string object with the value "Welcome" in string constant pool, so it will create a new object. After that it will find the string with the value "Welcome" in the pool, it will not create new object but will return the reference to the same instance. To make Java more memory efficient (because no new objects are created if it exists already in string constant pool).

### 2. By new keyword

```
String s=new String("Welcome");
```

In such case, JVM will create a new string object in normal (non pool) heap memory and the literal "Welcome" will be placed in the string constant pool. The variable s will refer to the object in heap (non pool).

The java String is immutable i.e. it cannot be changed. Whenever we change any string, a new instance is created. For mutable string, you can use `StringBuffer` and `StringBuilder` classes.

*The following program explains the creation of strings*

```
public class String_Example{
    public static void main(String args[])
    {
        String s1="java";
        char c[]={'s','t','r','i','n','g'};String s2=new String(c);
        String s3=new String("example");
        System.out.println(s1);
        System.out.println(s2);
        System.out.println(s3);
    }
}
```

### Java String class methods

The java.lang.String class provides many useful methods to perform operations on sequence of char values.

| Method   | Description   |
|--|---|
| char charAt(int index)   | returns char value for the particular index                     |
| int length()   | returns string length   |
| static String format(String format, Object... args)                  | returns formatted string  |
| static String format(Locale l, Stringformat, Object... args)         | returns formatted string with given locale                      |
| String substring(int beginIndex)                                     | returns substring for given begin index                         |
| String substring(int beginIndex, int endIndex)                       | returns substring for given begin index and end index           |
| boolean contains(CharSequence s)                                     | returns true or false after matching the sequence of char value |
| static String join(CharSequence delimiter, CharSequence... elements) | returns a joined string   |
| boolean equals(Object another)                                       | checks the equality of string with object                       |
| boolean isEmpty()  | checks if string is empty                                       |
| String concat(String str)  | concatenates specified string                                   |
| String replace(char old, char new)                                   | replaces all occurrences of specified char value                |

|  |  |
|--|--|
| String replace(CharSequence old, CharSequence new) | replaces all occurrences of specified CharSe- quence         |
| static String equalsIgnoreCase(String another)     | compares another string. It doesn't check case.              |
| String[] split(String regex)                       | returns splitted string matching regex                       |
| String[] split(String regex, int limit)            | returns splitted string matching regex and limit             |
| String intern()                                    | returns interned string                                      |
| int indexOf(int ch)                                | returns specified char value index                           |
| int indexOf(int ch, int fromIndex)                 | returns specified char value index starting with given index |
| int indexOf(String substring)                      | returns specified substring index                            |
| int indexOf(String substring, int fromIndex)       | returns specified substring index starting with given index  |
| String toLowerCase()                               | returns string in lowercase.                                 |
| String toLowerCase(Locale l)                       | returns string in lowercase using specified locale.          |
| String toUpperCase()                               | returns string in uppercase.                                 |
| String toUpperCase(Locale l)                       | returns string in uppercase using specified locale.          |
| String trim()                                      | removes beginning and ending spaces of this string.          |
| static String valueOf(int value)                   | converts given type into string. It is over- loaded          |

*The following program is an example for String concat function:*

```
class string_method{
    public static void main(String args[]){
        String s="Java";
        s=s.concat(" Programming");
        System.out.println(s);
    }
}
```

*Output:*

*Java Programming*
